Creating Heuristics

Creating Admissible Heuristics

- Most of the work in solving hard search problems optimally is in coming up with admissible heuristics
- Often, admissible heuristics are solutions to *relaxed problems*, where new actions are available

- Inadmissible heuristics are often useful too

Example: 8Puzzle

7	2	4
5		6
8	3	1

Start State

Actions

	1	2
3	4	5
6	7	8

Goal State

- What are the states?
- How many states?
- What are the actions?
- How many successors from the start state?
- What should the costs be?

8 Puzzle I

- Heuristic: Number of tiles misplaced
- Why is it admissible?
- $h(\text{start}) = 8$
- This is a *relaxed-problem* heuristic

7	2	4
5		6
8	3	1

Start State

	1	2
3	4	5
6	7	8

Goal State

8 Puzzle II

- What if we had an easier 8-puzzle where any tile could slide any direction at any time, ignoring other tiles?

- Total *Manhattan* distance

- Why is it admissible?

$$h(\text{start}) = 3+1+2 + \dots = 18$$

Start State

Goal State

8 Puzzle III

- How about using the *actual cost* as a heuristic?
 - Would it be admissible?
 - Would we save on nodes expanded?
 - What's wrong with it?

- With A*: a trade-off between quality of estimate and work per node
 - As heuristics get closer to the true cost, you will expand fewer nodes but usually do more work per node to compute the heuristic itself

Trivial Heuristics, Dominance

- Dominance: $h_a \leq h_c$ if

$$\forall n : h_a(n) \geq h_c(n)$$

- Heuristics form a semi-lattice:
 - Max of admissible heuristics is admissible

$$h(n) = \max(h_a(n), h_b(n))$$

- Trivial heuristics
 - Bottom of lattice is the zero heuristic)what does this give us(?)
 - Top of lattice is the exact heuristic

Graph Search

Tree Search: Extra Work!

- Failure to detect repeated states can cause exponentially more work.

Graph Search

- In BFS, for example, we shouldn't bother expanding the circled nodes (why?)

Graph Search

- Idea: never **expand** a state twice
- How to implement:
 - Tree search + set of expanded states ("closed set")
 - Expand the search tree node-by-node, but...
 - Before expanding a node, check to make sure its state has never been expanded before
 - If not new, skip it, if new add to closed set
- Important: **store the closed set as a set**, not a list
- Can graph search wreck completeness? Why/why not?
- How about optimality?

A* Graph Search Gone Wrong?

State space graph

Search tree

Consistency of Heuristics

- Main idea: estimated heuristic costs \leq actual costs
 - Admissibility: heuristic cost \leq actual cost to goal $h(A) \leq$ actual cost from A to G
 - Consistency: heuristic cost \leq actual cost for each arc $h(A) - h(C) \leq \text{cost}(A \text{ to } C)$
- Consequences of consistency:
 - The f value along a path never decreases $h(A) \leq \text{cost}(A \text{ to } C) + h(C)$
 - A* graph search is optimal

Optimality of A* Graph Search

- Sketch: consider what A* does with a consistent heuristic:
 - Fact 1: In tree search, A* expands nodes in increasing total f value (f -contours)
 - Fact 2: For every state s , nodes that reach s optimally are expanded before nodes that reach s suboptimally
 - Result: A* graph search is optimal

Optimality

- **Tree search:**
 - A* is optimal if heuristic is admissible
 - UCS is a special case ($h = 0$)
- **Graph search:**
 - A* optimal if heuristic is consistent
 - UCS optimal ($h = 0$ is consistent)
- **Consistency implies admissibility**
- **In general, most natural admissible heuristics tend to be consistent, especially if from relaxed problems**

A*: Summary

- A* uses both backward costs and (estimates of) forward costs
- A* is optimal with admissible / consistent heuristics
- Heuristic design is key: often use relaxed problems

Thanks
